

Autonomous Mobile Robots

Fabian Blöchliger

Spring Semester 2016

1 Introduction and Motivation

2 Locomotion Concepts

Express point P which is given w.r.t body frame B in inertial frame I :

$${}^I\mathbf{r}_{OP} = {}^I\mathbf{r}_{OB} + \mathbf{R}_{IB} {}^B\mathbf{r}_{BP}.$$

Equivalent **homogeneous transformation** description:

$$\begin{bmatrix} {}^I\mathbf{r}_{OP} \\ 1 \end{bmatrix} = \begin{bmatrix} \mathbf{R}_{IB} & {}^I\mathbf{r}_{OB} \\ 0 & 1 \end{bmatrix} \begin{bmatrix} {}^B\mathbf{r}_{BP} \\ 1 \end{bmatrix} = \mathbf{H}_{IB} \cdot {}^B\tilde{\mathbf{r}}_{BP}.$$

Velocity of rigid body point P :

$${}^I\mathbf{v}_P = {}^I\dot{\mathbf{r}}_{OP} = \dot{\mathbf{r}}_{OB} + I\omega_{IB} \times {}^I\mathbf{r}_{BP}.$$

Differentiation in moving frame (**Coriolis equation**):

$${}^B\mathbf{v}_P = {}^B[\dot{\mathbf{r}}_{OP}] = \frac{d}{dt} {}^B\mathbf{r}_{OP} + {}^B\omega_{IB} \times {}^B\mathbf{r}_{OP}$$

Basic rotation matrices $\mathbf{R}_x(\bullet)$, $\mathbf{R}_y(\bullet)$, $\mathbf{R}_z(\bullet)$:

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos & -\sin \\ 0 & \sin & \cos \end{bmatrix}, \begin{bmatrix} \cos & 0 & \sin \\ 0 & 1 & 0 \\ -\sin & 0 & \cos \end{bmatrix}, \begin{bmatrix} \cos & -\sin & 0 \\ \sin & \cos & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Jacobian (partial derivative of position vector $\mathbf{r}(\mathbf{q})$ w.r.t. **generalized coordinate** vector \mathbf{q}):

$$\mathbf{J} = \frac{\partial \mathbf{r}(\mathbf{q})}{\partial \mathbf{q}} = \begin{bmatrix} \frac{\partial r_1}{\partial q_1} & \dots & \frac{\partial r_1}{\partial q_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial r_m}{\partial q_1} & \dots & \frac{\partial r_m}{\partial q_n} \end{bmatrix}.$$

Left/right pseudoinverse for $m \times n$ matrix \mathbf{J} to solve $\mathbf{r}_F = \mathbf{J}_F \mathbf{q}$ for \mathbf{q} :

$$\mathbf{J}^+ = \begin{cases} (\mathbf{J}^T \mathbf{J})^{-1} \mathbf{J}^T, & m > n \text{ (overdetermined)}, \\ \mathbf{J} (\mathbf{J} \mathbf{J}^T)^{-1}, & m < n \text{ (underdetermined)}. \end{cases}$$

Iterative approach for **inverse kinematics** of robotic manipulator to find generalized coordinates for end-effector position \mathbf{r}^{goal} (Newton's method):

$$\begin{aligned} \mathbf{q} &= \mathbf{q}^0, \mathbf{r} = \mathbf{r}(\mathbf{q}) \\ \text{while } \|\mathbf{r} - \mathbf{r}^{\text{goal}}\| > \text{threshold} \text{ do} \\ &\quad \mathbf{q} = \mathbf{q} + \mathbf{J}^+(\mathbf{q}) \cdot (\mathbf{r}^{\text{goal}} - \mathbf{r}), \quad \mathbf{r} = \mathbf{r}(\mathbf{q}) \end{aligned}$$

Inverse **differential kinematics** (get desired end-effector velocity $\dot{\mathbf{r}}_F$):

$$\dot{\mathbf{r}}_F = \mathbf{J}_F \dot{\mathbf{q}} \rightarrow \dot{\mathbf{q}} = \mathbf{J}_F^+ \dot{\mathbf{r}}_F.$$

3 Mobile Robot Kinematics

General wheel equation ($\mathbf{v}_{IR}, \omega_{IR}$: linear / angular robot velocity, ω_{RS} : steer rate, \mathbf{r}_{SW} : wheel offset):

$$\mathbf{v}_{IW} = \mathbf{v}_{IR} + \omega_{IR} \times [\mathbf{r}_{RS} + \mathbf{r}_{SW}] + \omega_{RS} \times \mathbf{r}_{SW}.$$

Standard wheel equation (no wheel offset \mathbf{r}_{SW}):

$$\mathbf{v}_{IW} = \mathbf{v}_{IR} + \omega_{IR} \times \mathbf{r}_{RS}.$$

Rolling constraint ($\mathbf{w}_W \mathbf{v}_{IW} = [0, -r\dot{\varphi}, 0]^T$):

$$\begin{bmatrix} \sin(\alpha + \beta) & -\cos(\alpha + \beta) & (-l) \cos(\beta) \end{bmatrix} R(\theta) \dot{\xi}_I = r\dot{\varphi}.$$

No-sliding constraint:

$$\begin{bmatrix} \cos(\alpha + \beta) & \sin(\alpha + \beta) & l \sin(\beta) \end{bmatrix} R(\theta) \dot{\xi}_I = 0.$$

Robot state: $\xi_I = [x \ y \ \theta]^T$, $\dot{\xi}_R = R(\theta) \dot{\xi}_I$, $R(\theta) = \mathbf{R}_z^T(\theta)$.

Stacked equations of motion for a $(N_f + N_s)$ -wheeled robot:

$$\begin{aligned} \text{(rolling)} \quad & \begin{bmatrix} J_1(\beta_s) \\ C_1(\beta_s) \end{bmatrix} R(\theta) \dot{\xi}_I = \begin{bmatrix} J_2 \\ 0 \end{bmatrix} \dot{\varphi}, \quad \dot{\varphi} = [\varphi_1 \dots \varphi_N], \\ \text{(no-sliding)} \quad & \end{aligned}$$

with

$$J_1(\beta_s) = \begin{bmatrix} J_{1f} \\ J_{1s}(\beta_s) \end{bmatrix}, J_2 = \text{diag}(r_1 \dots r_N), C_1(\beta_s) = \begin{bmatrix} C_{1f} \\ C_{1s}(\beta_s) \end{bmatrix}.$$

A robot's **degree of maneuverability** φ_M is

$$\delta_M = \delta_m + \delta_s,$$

which is the sum of its **degree of mobility** φ_m and its **degree of steerability** φ_s :

$$\delta_m = \dim N[C_1(\beta_s)] = 3 - \text{rank}[C_1(\beta_s)], \quad \varphi_s = \text{rank}[C_{1s}(\beta_s)].$$

Forward/inverse kinematics of a **differential drive robot**:

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{\theta} \end{bmatrix} = \begin{bmatrix} \frac{r}{2} & \frac{r}{2} \\ 0 & 0 \\ \frac{r}{2b} & -\frac{r}{2b} \end{bmatrix} \begin{bmatrix} \dot{\varphi}_r \\ \dot{\varphi}_l \end{bmatrix} \quad / \quad \begin{bmatrix} \dot{\varphi}_r \\ \dot{\varphi}_l \end{bmatrix} = \begin{bmatrix} \frac{1}{r} & 0 & \frac{b}{r} \\ \frac{1}{r} & 0 & -\frac{b}{r} \end{bmatrix} \begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{\theta} \end{bmatrix}.$$

4 Perception I

Sensor Type	System	Class
Tactile	Bumpers	EC, P
Wheel/motor	Brush encoders	PC, P
	Optical encoders	PC, A
	Heading	EC, P
Heading	Compass	EC, P
	Gyroscope	PC, P
	Inclinometer	EC, A/P
Acceleration	Accelerometer	PC, P
	Beacons	EC, A
Range	Radio, ultrasonic, Reflective Beacons	EC, A
	Motion/speed	Doppler: radar/sound EC, A
	Range	Ultrasound, laser, struct. light, ToF EC, A
Vision	CCD/CMOS	EC, P

(PC = **proprioceptive**, EC = **exteroceptive**, A = active, P = passive)

Range sensors: Traveled distance d of a sound or electromagnetic wave after a **time of flight** t is given by

$$d = ct, \quad c = 0.3 \text{ m/ms (sound)} / 0.3 \text{ m/ns (light)}.$$

The **mean/expectation value** $E[x] = \mu$ and the **variance** $\text{Var}[x] = \sigma^2$ of a **continuous random variable** x with **probability density function (PDF)** $p(x)$ are computed as

$$\mu = \int_{-\infty}^{\infty} xp(x)dx, \quad \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 p(x)dx.$$

The PDF for a one-dimensional **Gaussian distribution**:

$$p(x) = \mathcal{N}(\mu, \sigma^2) = \frac{1}{\sigma\sqrt{2\pi}} \exp \left[-\frac{(x - \mu)^2}{2\sigma^2} \right].$$

The **error propagation law** describes the mapping from input covariance C_X to output covariance C_Y using the Jacobian F_X of the mapping function $f(\bullet) : \mathbb{R}^n \rightarrow \mathbb{R}^m$ w.r.t. X :

$$C_Y = F_X C_X F_X^T \quad (\text{linear approximation}).$$

5 Perception II

Thin lens equation: Voxel at depth z will be **focused** on the **focal plane** at distance e behind the lens for a camera with **focal length** f . If the **image plane** lies at $e \pm \delta$, the voxel image will be a **blur circle** of radius R :

$$\frac{1}{f} = \frac{1}{z} + \frac{1}{e}, \quad R = \frac{L\delta}{2e} \quad (L : \text{diameter of lens/aperture}).$$

Pinhole approximation: $z \gg f$, therefore $e \approx f$ (lens is approximated as pinhole at distance f from image plane).

Perspective projection: A 3D-point $P_C = [X_C, Y_C, Z_C]^\top$ (in camera frame C) projects onto the image location $[u, v]^\top$ as

$$\begin{bmatrix} u \\ v \\ 1 \end{bmatrix} = \begin{bmatrix} \alpha_u X_C / Z_C + u_0 \\ \alpha_v Y_C / Z_C + v_0 \end{bmatrix} \quad / \quad \lambda \begin{bmatrix} u \\ v \\ 1 \end{bmatrix} = \underbrace{\begin{bmatrix} \alpha_u & 0 & u_0 \\ 0 & \alpha_v & v_0 \\ 0 & 0 & 1 \end{bmatrix}}_{\text{calibr. matrix } K} \begin{bmatrix} X_C \\ Y_C \\ Z_C \end{bmatrix},$$

with $[\alpha_u, \alpha_v] = f[k_u, k_v]$, using the inverse of the effective pixel size k_u (k_v) in [pixel/m] and the pixel coordinates of the **optical center** $[u_0, v_0]^\top$. K contains the **intrinsic parameters**.

Radial distortion model:

$$\begin{bmatrix} u_d \\ v_d \end{bmatrix} = (1 + k_1 r^2) \begin{bmatrix} u - u_0 \\ v - v_0 \end{bmatrix} + \begin{bmatrix} u_0 \\ v_0 \end{bmatrix}, \quad r^2 = (u - u_0)^2 + (v - v_0)^2.$$

For a **general perspective projection**, P_W is given w.r.t. world frame W and the transform from W to C is described by the **extrinsic parameters** $[R|T]$.

$$\lambda \begin{bmatrix} u \\ v \\ 1 \end{bmatrix} = K \left(R \begin{bmatrix} X_W \\ Y_W \\ Z_W \end{bmatrix} + T \right) = \underbrace{K[R|T]}_{\text{camera matrix } P} \begin{bmatrix} X_W \\ Y_W \\ Z_W \\ 1 \end{bmatrix}.$$

Basic stereo camera setup with **baseline** b and focal length f , the depth Z for a point at left/right coordinate $[u_l, u_r]$ is

$$Z = bf/d, \quad d = u_l - u_r \quad (\text{disparity}).$$

Cross-product written with skew-symmetric matrix:

$$\mathbf{a} \times \mathbf{b} = [\mathbf{a}_\times] \mathbf{b} = \begin{bmatrix} 0 & -a_z & a_y \\ a_z & 0 & -a_x \\ -a_y & a_x & 0 \end{bmatrix} \begin{bmatrix} b_x \\ b_y \\ b_z \end{bmatrix}.$$

Epipolar constraint (p_1, p_2 : normalized, homogeneous):

$$p_2^\top E p_1 = 0, \quad E = [T_\times] R \quad (\text{essential matrix}).$$

6 Perception III

Correlation with a filter/kernel/mask F of size $(2N + 1)$ is

$$J(x) = F \circ I(x) = \sum_{i=-N}^N F(i) I(x + i),$$

Convolution is correlation with a flipped filter:

$$J(x) = F * I(x) = \sum_{i=-N}^N F(i) I(x - i).$$

In contrast to correlation, convolution is associative.

Linear filters replace every pixel by a linear combination of its neighbors. **Shift-invariant filters** perform the same operation on every point of the image.

The **2D Gaussian kernel** is a **separable filter** (width σ):

$$G_\sigma(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} = \underbrace{\frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}}}_{g_\sigma(x)} \cdot \underbrace{\frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{y^2}{2\sigma^2}}}_{g_\sigma(y)}.$$

Laplacian of Gaussian (second derivative operator):

$$\text{LoG} = \nabla^2 G_\sigma(x, y) = \frac{\partial^2 G_\sigma(x, y)}{\partial x^2} + \frac{\partial^2 G_\sigma(x, y)}{\partial y^2}.$$

Difference of Gaussian is an approximation of LoG:

$$\text{DoG} = G_{k\sigma}(x, y) - G_\sigma(x, y).$$

Template matching using **sum of squared differences**:

$$\begin{aligned} \text{SSD}(x) &= \sum_{i=-N}^N [F(i) - I(x + i)]^2, \\ &= \sum [F(i)]^2 + \sum [I(x + i)]^2 - 2 \sum [F(i) I(x + i)]. \end{aligned}$$

Sobel masks as approximate derivative filters:

$$I_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}, \quad I_y = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}.$$

The **second order matrix** used by the **Harris corner detector** (image patch size P):

$$M = \sum_{x, y \in P} \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix}, \quad \text{SSD}(\Delta x, \Delta y) \approx [\Delta x \ \Delta y] M \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}.$$

Corners: Local maxima in the **cornerness function**

$$C = \lambda_1 \lambda_2 - \kappa (\lambda_1 + \lambda_2)^2 = \det M - \kappa \text{trace}^2 M.$$

Main **SIFT** stages:

1. Extract keypoints + scale.
2. Assign keypoint orientation.
3. Generate descriptor (4·4·8).
4. Matching (L_2 distance).

7 Perception IV

Vector quantization by **k-means clustering**, minimizes squared Euclidean distance between points and their nearest cluster-centers:

```

randomly initialize  $k$  cluster centers
while not converged do
    assign each vector to nearest center
    re-compute cluster centers
    
```

Robust model fitting with **RANSAC** (RANDOM Sample Consensus) to find a point set free of outliers with probability p with a known fraction of inliers w :

```

for  $k \leftarrow 1$  to  $\frac{\log(1-p)}{\log(1-w^2)}$  do
    randomly select minimal sample data points
    calculate corresponding model parameters
    calculate error function for each data point
    select data that supports current hypothesis
    
```

Line extraction using the **Hough transform**: Map point (x, y) to sinusoid in (θ, ρ) parameter space according to

$$x \cos \theta + y \sin \theta = \rho.$$

8 Localization I

Sum rule (1) and **product rule** (2):

$$(1) p(x) = \sum_y p(x, y), \quad (2) p(x, y) = p(y|x)p(x).$$

Combine them to get the **theorem of total probability**:

$$p(x) = \sum_y p(y|x)p(x).$$

Assuming that $p(y) > 0$, **Bayes' rule** is

$$p(x|y) = \frac{p(y|x)p(x)}{p(y)} = \eta p(y|x)p(x), \quad \eta = p(y)^{-1}.$$

Multivariate Gaussian distribution $\mathcal{N}(\mu, \Sigma)$ for dimension k with (symmetric) covariance matrix Σ :

$$p(x) = \frac{1}{(2\pi)^{k/2} \det(\Sigma)^{1/2}} \exp \left[-\frac{1}{2} (x - \mu)^\top \Sigma^{-1} (x - \mu) \right].$$

Combination of GRVs: Let $y = Ax_1 + Bx_2$ be a linear function of $x_i = \mathcal{N}(\mu_i, \Sigma_i)$. Then, $p(y)$ is

$$p(y) = \mathcal{N}(A\mu_1 + B\mu_2, A\Sigma_1A^\top + B\Sigma_2B^\top).$$

If $y = f(x_1, x_2)$ is non-linear, approximate y and $p(y)$ as

$$y \approx f(\mu_1, \mu_2) + F_{x_1}(x_1 - \mu_1) + F_{x_2}(x_2 - \mu_2),$$

$$p(y) \approx \mathcal{N}(f(\mu_1, \mu_2), F_{x_1}\Sigma_1F_{x_1}^\top + F_{x_2}\Sigma_2F_{x_2}^\top).$$

A robot's **belief** about its state x_t before/after measurement z_t is represented as probability distribution:

$$\bar{bel}(x_t) = p(x_t|z_{1 \rightarrow t-1}, u_{1 \rightarrow t}), \quad bel(x_t) = p(x_t|z_{1 \rightarrow t}, u_{1 \rightarrow t}).$$

Ingredients of probabilistic **map-based localization**:

1. The initial probability distribution $bel(x_0)$.
2. **True map** $M = \{m_0 \dots m_n\}$ of the environment.
3. Data: u_t (proprioceptive, control), z_t (exteroceptive).
4. Probabilistic **motion model** $p(x_t|u_t, x_{t-1})$, e.g. based on noise-free model $x_t = f(x_{t-1}, u_t)$.
5. Probabilistic **measurement model** $p(z_t|x_t, M)$, e.g. based on noise-free model $z_t = h(x_t, M)$.

Classification of localization problems:

- **Position tracking:** $bel(x_0)$ is **Dirac delta** function.
- **Global localization:** Uniform distribution for $bel(x_0)$.
- **Kidnapped robot problem:** Does the robot realize?

Architecture map:

Exact cell decomposition:

Approx. decomposition:

Topological:

9 Localization II

According to the **Markov assumption**, the robot's belief state $bel(x_t)$ is a function only of robot's previous state x_{t-1} and its most recent actions u_t and observations z_t :

$$p(x_t|x_0, u_0 \dots u_t, z_0 \dots z_t) = p(x_t|x_{t-1}, u_t, z_t).$$

The general algorithm for **Markov localization**:

for all x_t **do**

$$\left[\begin{array}{ll} \bar{bel}(x_t) = \sum_{x_{t-1}} p(x_t|u_t, x_{t-1}) bel(x_{t-1}) & \text{(prediction)} \\ bel(x_t) = \eta p(z_t|x_t, M) \bar{bel}(x_t) & \text{(measurement)} \end{array} \right.$$

Kalman filter localization assumes $bel(x_t) = \mathcal{N}(x_t, P_t)$.

S1) The **prediction update** is (Q_t : covariance of motion model noise, $F_{x/u}$: jacobian w.r.t. x/u):

$$\hat{x}_t = f(x_{t-1}, u_t), \quad \hat{P}_t = F_x P_{t-1} F_x^\top + F_u Q_t F_u^\top.$$

S2) The **measurement update** consists of four steps:

1. **Observation:** Obtain z_t^i with covariance R_t^i ($i = 1..n$).
2. **Measurement prediction:** Predict $\hat{z}_t^j = h^j(\hat{x}_t, m^j)$, compute its jacobian H^j w.r.t. \hat{x}_t .
3. **Matching step:** Compute the **innovation (covariance)**

$$v_t^{ij} = [z_t^i - \hat{z}_t^j], \quad \Sigma_{IN_t}^{ij} = H^j \hat{P}_t H^{j\top} + R_t^i,$$

Find matches with a **validation gate** g , e.g. Mahalanobis distance: $v_t^{ij\top} (\Sigma_{IN_t}^{ij})^{-1} v_t^{ij} \leq g^2$.

4. **Estimation step:** Stack validated observations into z_t , corresponding innovations into v_t , measurement jacobians into H_t and $R_t = \text{diag}(R_t^i)$, compute Σ_{IN_t} . Update the robot's state estimate as

$$x_t = \hat{x}_t + K_t v_t, \quad P_t = \hat{P}_t - K_t \Sigma_{IN_t} K_t^\top,$$

with the **Kalman gain**

$$K_t = \hat{P}_t H_t^\top (\Sigma_{IN_t})^{-1}.$$

12 Planning I

Dynamic window approach (DWA): Acts in input space (v, ω) . Set of admissible velocities within next time frame is

$$V_r = \underbrace{V_o}_{\text{grid, obstacles (in input-space)}} \cap \underbrace{V_s}_{\text{static window (motor limits etc.)}} \cap \underbrace{V_d}_{\text{dynamic window (feasible within next frame)}}$$

Maximize $(v, \omega) \in V_r$, subject to (local) objective function

$$O = a \cdot \text{heading}(v, \omega) + b \cdot \text{velocity}(v, \omega) + c \cdot \text{obst_dist}(v, \omega).$$

Velocity obstacles (VO): 1) Compute set of colliding velocities. 2) Restrict to set of colliding velocities within time horizon τ . 3) Shift VO by instantaneous obstacle velocity.

$$\|\mathbf{p}_{RO} + \mathbf{v}_R t\| < r_R + r_O, \quad \text{VO}_{RO}^\tau = \bigcup_{0 \leq t \leq \tau} \text{Disks}\left(-\frac{\mathbf{p}_{RO}}{t}, \frac{r_{RO}}{t}\right).$$

Interactive collision avoidance for multiple decision-making agents without explicit communication, using a fairness property: **reciprocal velocity obstacles**.

Local potential fields: Robot (position \mathbf{q}) follows gradient of potential field. Potential attractive at goal, repulsive at obstacles ($U_{\text{rep}} = 0$ if distance to obstacle $\rho(\mathbf{q}) > \rho_{\text{lim}}$):

$$U_{\text{att}}(\mathbf{q}) = \frac{1}{2} k_{\text{att}} (\mathbf{q} - \mathbf{q}_{\text{goal}})^2, \quad U_{\text{rep}}(\mathbf{q}) = \frac{1}{2} k_{\text{rep}} \left(\frac{1}{\rho(\mathbf{q})} - \frac{1}{\rho_{\text{lim}}} \right)^2.$$

Harmonic potential fields: Iteratively solve the **Laplace equation** $\Delta U = \sum \frac{\partial^2 U}{\partial q_i^2} = 0$ with the approximation $\nabla U(\mathbf{q})_i \approx [U(\mathbf{q} + \delta \mathbf{e}_i) - U(\mathbf{q})]/\delta$ as

$$U^{k+1}(\mathbf{q}) = \frac{1}{2n} \sum_{i=1}^n (U^k(\mathbf{q} + \delta \mathbf{e}_i) + U^k(\mathbf{q} - \delta \mathbf{e}_i)),$$

with a mixture of the following boundary conditions concerning the obstacle boundaries:

- **Neumann:** Equipotential lines orthogonal.
- **Dirichlet:** Constant potential.

Additional obstacle avoidance examples:

- **Bug algorithm:** Follow the boundary of an obstacle, depart from point of shortest distance to the goal.
- **Vector field histogram (VHF):** Use polar histogram showing probability of obstacle occurrence.
- **Bubble band technique:** Compute bubbles representing max. free space around given robot configuration.

13 Planning II

Road map approaches for construction of graph $G(N, E)$ with nodes N and edges E :

- **Visibility graph:** Connect nodes (obstacle corners) that see each other. Optimal solutions w.r.t path length.
- **Voronoi diagram:** Evaluate equidistant paths to obstacles, workspace needs to be closed.

General **deterministic graph search** algorithm:

```
Queue.init(), Queue.push(Start)
while Queue is not empty do
    Node curr = Queue.pop()
    if curr is Goal return
    Closed.push(curr); Nodes next = expand(curr)
    for all next not in Closed do
        Queue.push(next)
```

Total expected cost from start to goal via node N :

$$f(N) = \underbrace{g(N)}_{\text{cost so far (from start)}} + \varepsilon \cdot \underbrace{h(N)}_{\text{heuristic cost-to-go}}.$$

Examples:

- 1) **Breadth-first search:** FIFO queue, solution optimal for uniform edge costs, complexity: $\mathcal{O}(|N| + |E|)$.
- 2) **Depth-first search:** LIFO queue, solution not optimal.
- 2) **Dijkstra's search:** ordering according to $f(N)$ with $\varepsilon = 0$, complexity: $\mathcal{O}(|N| \log |N| + |E|)$.
- 3) **A* algorithm:** extension of Dijkstra with $\varepsilon = 1$. Possible heuristic $h(N)$: Euclidean distance to goal (underestimation).
- 4) **D* algorithm:** incremental replanning version of A*.

Binary min-heap: Top node has minimum value.

- *Push(N):* Insert new node N at end of heap. While $N < \text{parent}(N)$, swap N and $\text{parent}(N)$.
- *Pop():* Return top element of heap. Move bottom node N to top. While $N < \min(\text{child}(N))$, swap these nodes.

Rapidly exploring random tree (RRT) algorithm as an example of a randomized graph search method:

```
Graph.init(Start)
while Graph.size() is less than threshold do
    Node rand = rand()
    Node near = Graph.nearest(rand)
    try
        Node new = Sys.propagate(near, rand)
        Graph.addNode(new)
        Graph.addEdge(near, new)
```
